Abstract

How do concepts of mental life vary across cultures? By asking simple questions about humans, animals, and other entities – for example, 'Do beetles get hungry? Remember things? Feel love?'

Yet there were substantial cultural and developmental differences in the status of social emotional abilities as part of the body, part of the mind, or a third category unto themselves. Such differences may have far-reaching social consequences, whereas the similarities identify aspects of human understanding that may be universal.

We reconstructed concepts of mental life from the bottom up among adults ($n = 711$) and children (ages 6–12 years, $n = 693$) in the USA, Ghana, Thailand, China, and Vanuatu. This revealed a cross-cultural and developmental continuity: in all sites, among both adults and children, cognitive abilities travelled separately from bodily sensations, suggesting that a mind–body distinction is common across diverse cultures and present by middle childhood.

Computational repeatability test of the results of the Kara Weisman (2021) study*

1 Introduction

1.1 Selected Literature

Title: Similarities and differences in concepts of mental life among adults and children in five cultures.

Weisman, K., Legare, C. H., Smith, R. E., Dzokoto, V. A., Aulino, F., Ng, E., … & Luhrmann, T. M. (2021). Similarities and differences in concepts of mental life among adults and children in five cultures. *Nature Human Behaviour*, *5*(10), 1358-1368. (APA)

We adopted the code from:
https://github.com/kgweisman/mental-life-culture-development.

1.2 Introduction to Literature

1.2.1 Research Background. Understanding mental life (thoughts, emotions, intentions, etc.) is crucial for social life, as it helps us predict and explain others' behaviors. Research in cultural psychology and anthropology suggests that there are differences in how mental life is understood across cultures.

1.2.2 Main Research Questions and Hypotheses. This study explores how adults and children from different cultural backgrounds understand concepts of mental life. It hypothesizes that these understandings have certain universal aspects but may show significant differences in social-emotional abilities.

1.2.3 Research Results and Conclusions. The study found that cognitive abilities travelled separately from bodily sensations among both adults and children in all sites, suggesting that a mind–body distinction is common across diverse cultures and present by middle childhood. Yet there were substantial cultural and developmental

differences in the status of social–emotional abilities – as part of the body, part of the mind or a third category unto themselves. These findings suggest that while some aspects of mental life may be universal, the influences of culture and development significantly shape the understanding of social-emotional abilities (Weisman et al., 2021).

2 Methods

2.1 Introduction to the Original Research Methods

2.1.1 Participants. The study involved participants from five diverse cultural settings: - San Francisco Bay Area, USA - Cape Coast, Ghana - Chiang Mai, Thailand - Shanghai, China - Port Vila and Malekula, Vanuatu.

The total sample consisted of 711 adults and 693 children aged 6-12 years. Adults were primarily recruited in public places, and children were recruited from elementary schools (Weisman et al., 2021).

2.1.2 Data Analysis. Exploratory factor analysis (EFA) was used to identify underlying constructs and the number of factors retained was determined by parallel analysis. Factor similarities between different cultures and age groups were compared by vector cosine (rc). The details are as follows: - Exploratory factor analysis (EFA) was used to identify latent constructs or core components of the concept of mental life within each cultural sample. - Parallel analysis determined the number of factors to retain, and oblique transformation was used to interpret factor loadings. - Comparisons across cultural sites and age groups were made using vector cosine (rc) calculations to gauge the similarity of factors (Weisman et al., 2021).

2.2 Reproduction Ideas and R Packages

2.2.1 R Packages. Install and load necessary R packages, including `dplyr` (Wickham, François, Henry, Müller, & Vaughan, 2023), `tidyr` (Wickham, Vaughan, &

Girlich, 2023), `ggplot2` (Wickham, 2016), `papaja` (Aust & Barth, 2023), `tidyverse` (Wickham et al., 2019), `lubridate` (Grolemund & Wickham, 2011), `readxl` (Wickham & Bryan, 2023), `psych` (William Revelle, 2023), `cowplot` (Wilke, 2020), `here` (Müller, 2020), `reshape2` (Wickham, 2007), `sjstats` (Lüdecke, 2024), `lsa` (Wild, 2022), `langcog` (Braginsky, Yurovsky, & Frank, 2024), `GPArotation` (Bernaards & Jennrich, 2005), `irr` (Gamer, Lemon, & <puspendra.pusp22@gmail.com>, 2019), `kableExtra` (Zhu, 2024), and `janitor` (Firke, 2023).

2.2.2 Reproduction Ideas.

- **Clean and preprocess the data:** Since the author does not provide raw data, only the code for data preprocessing, there is no data preprocessing part in our reproduction.
- **Main Analysis:** Exploratory Factor Analysis (EFA) using Pearson correlation and oblique rotation (the analysis mentioned in the main text of the paper, which is our focus for replication).
- **Secondary Analyses (mentioned in the supplementary materials of the paper):**
- Using orthogonal rotation instead of oblique rotation.
- Equating “somewhat” responses to “yes” and using tetrachoric correlation.
- Excluding participants who provided the same answer (e.g., all “yes” or all “no”) in every trial.
- Using Principal Component Analysis (PCA) instead of Exploratory Factor Analysis (EFA).
- Incorporating demographic variables in the covariance model.

2.2.3 Verification and Comparison.

- Compare the replicated results with the original findings.
- Identify any discrepancies and investigate potential reasons for these differences.
- Document the replication process, including any challenges encountered and how they were addressed (Weisman et al., 2021).

2.2.4 Programming Environment. All analyses by the authors were conducted in the R version 4.0.0 environment, on the x86_64-apple-darwin17.0 (64-bit) platform, with macOS Catalina 10.15.7 as the operating system.

All our analyses were conducted in the R version 4.3.1 environment, on the arm64-apple-darwin platform, with macOS Sonoma 14.5 as the operating system (R Core Team, 2023).

3 Replication Results

In this section, we present the results of our replication study. The analyses were conducted following the methodologies described in the original research by Weisman et al. (2021). We compare our findings with the original results to assess the reproducibility of the study's conclusions.

3.1 Data preparation

The data was read from adults and children in five different cultural settings. It filtered the data to include only universal targets and questions, shortened the descriptions of the questions, and for children, it additionally filtered the age range to 6-12 years. Next, the preprocessed data was converted to a wide format. This transformation was performed separately for both adult and children datasets across the five cultural settings, making the data suitable for subsequent Exploratory Factor Analysis (EFA).

3.5 Repeatability test results

4 Discussion

4.1 Analysis of the results of the computational reproducibility test

We successfully replicated the factor structure of adult and child conceptualizations of psychological abilities across five cultures as reported by Weisman et al. (2021), and observed similar cross-cultural and cross-age-group patterns. Specifically, we arrived at the following conclusions:

- **Cross-Cultural Consistency:** Both adults and children clearly differentiated between somatic sensations and cognitive abilities in all five cultures, aligning with the original study's conclusions.
- **Cross-Age-Group Differences:** We noted significant differences in social affective capabilities between children and adults across the five cultures, supporting the original study's findings.

Upon comparing our replication results with the original study, we identified minor discrepancies that may stem primarily from the R environment and package versions. We further explored the similarity between adult factors in different countries and those in the U.S., as well as the similarity between child factors in different countries and those of local adults, to investigate structural differences in psychological life across cultures and age groups.

Our analysis indicates that descriptive statistics, cross-cultural comparisons, and developmental comparisons align with the original study. However, we observed slight deviations in individual values in the variance explained by factors and the correlation between adult and child factors.

We conducted our data analysis using R version 4.3.1, while the original study was based on R version 4.0.0. Additionally, updates to software packages may lead to deprecated functions, contributing to minor differences in results due to variations in programming environments and software package versions. To enhance result consistency, we will ensure stable package versions in future research, regularly updating and testing the R packages used to prevent similar issues.

In conclusion, our research findings support the conclusions of Weisman et al. (2021), demonstrating the existence of universal patterns in the conceptualization of psychological abilities across cultures and age groups, providing essential insights for understanding the cultural and developmental foundations of human psychology.

P.S.: Due to the substantial amount of numerical values involved in the EFA factor loading heatmaps in the main text of the paper, we did not calculate reproducibility results for them. Tables 1 to 17 do not encompass comparisons for all replicated results. However, through our replication of the figures in the paper, it is evident that our results align with the heatmaps created by the authors.

表 18. 计算可重复性的评估表

可重复性情况	数量及占比	
	N	%
完全一致($\delta = 0\%$)	248	97.63%
偏差较小($0\% < \delta < 10\%$)	2	0.78%
偏差较大($\delta > 10\%$)	4	1.57%
因舍入导致的偏差	0	0%

4.2 Summary of replication experience

The members of this group have also learned a lot through the reproduction of the data code in Weisman et al.'s paper, and based on their sharing, this section will summarize the key points of everyone's experience and experience

1. **Understanding Code Overview**:
    - Avoid using the `source()` function in R Markdown to prevent automatic execution of loaded R scripts. Manual review of R scripts helps in comprehensively understanding the authors' data analysis approach.
2. **Distinguishing `require` and `library` Functions**:
    - Use `require(package)` to return FALSE if the package is missing or fails to load, while `library(package)` halts execution if loading fails. Understanding this distinction is crucial for script continuity.
3. **Custom Functions and Scripts**:
    - Authors often create custom functions in separate scripts for data processing, exploratory factor analysis, regression analysis, reliability analysis, scoring, and visualization. Enhancing code modularity and readability.
4. **Data Preprocessing**:
    - Excluding specific data files or directories containing "raw" in their names, as indicated in the .gitignore file, is common practice. Understanding the authors' data preprocessing steps is essential for successful replication.
5. **Coding Style and `%>%` Pipe Operator**:
    - Familiarize with authors' coding style, including using the `%>%` pipe operator from the dplyr package for smoother and more readable data processing. The pipe operator facilitates chaining operations and streamlines code.

6. **Visualization in R Markdown**:

   - When plotting with ggplot2 in R Markdown, pay attention to saving graphs using `ggsave()` due to differences in display panes between R Markdown and R scripts.

7. **Interdisciplinary Insights**:

   - Compare psychological research in the paper with the philosophical "Three Worlds" theory to derive insights from other disciplines. Avoid relying solely on internal disciplinary assumptions in psychological research and consider adopting bottom-up research methods, especially in fields susceptible to researcher bias.

8. **R Language Learning Experience**:

   - Utilize forums, university websites, and other resources to deepen understanding of unfamiliar terms, theoretical concepts, and analytical tools' usage, while staying updated on subject-specific research group discussions.

9. **PPT Design and Presentation Skills**:

   - Emphasize concise and information-rich PPT design with logical coherence and clear structure. Avoid excessive text and prioritize the use of images for effective information presentation.
